Equine Infectious Anemia

Last Modified:

Equine infectious anemia (EIA) is a viral, and sometimes fatal, disease that only affects equids (horses, ponies, zebras, mules, and donkeys). There is no treatment. EIA can be difficult to recognize and may be confused with other diseases. It is found in nearly all countries worldwide, including the United States. It is a reportable animal disease in all States. It is not a threat to human health.

Clinical signs range from mild to severe and appear within a few weeks after infection. However, it may take 60 days or more for the horse to test positive.

Infected animals that survive the disease become virus carriers and can infect other equids for life. They must either be euthanized or permanently isolated from other equids to prevent transmission. Carriers may also experience clinical flare-ups, often following stress or strenuous work.

What To Look For

- Fever
- Decreased appetite
- Severe anemia
- Sudden death
- Jaundice (yellow discoloration of mucous membranes)
- Rapid breathing, rapid heart rate
- Swollen limbs
- Bleeding from the nose or red/purple spots on mucous membranes
- Blood-stained feces

Chronically infected horses may show no clinical signs.

How To Prevent This Disease

Biting, blood-feeding flies, such as horseflies or deerflies, can spread the virus from one animal to another. Historically, this has been the primary way EIA has spread. Animals can also get the virus from unclean or re-used needles and syringes, blood transfusions, and contaminated instruments, such as IV sets, dental instruments, and tattoo equipment. This type of human-facilitated transmission is now the most common way EIA spreads in the United States, particularly among current or former Quarter Horse racehorses, many with ties to unsanctioned (bushtrack) racing.

To prevent the spread of this disease:

- Control biting flies on your property to reduce your animal's exposure.

- Never reuse needles, syringes, or IV sets.
- Only use licensed and approved blood products.
- Make sure blood transfusions are performed only by licensed veterinarians using blood products from donor horses that have tested negative for EIA and other blood-borne infections like [equine piroplasmosis](#).
- Test your horses, ponies, mules, and donkeys annually for EIA.
- Call your veterinarian if you suspect EIA in any equid. Immediately move horses, ponies, mules, or donkeys that you think might have EIA at least 200 yards away from other equids on your property.

How It Is Treated

There is no treatment or vaccine. Because infected animals become lifelong carriers, they must be permanently isolated and quarantined or euthanized.

Report Signs of Animal Disease

Producers or owners who suspect an animal disease should contact their veterinarian to evaluate the animal or herd. [Find an accredited veterinarian](#).

Animal health professionals (veterinarians; diagnostic laboratories; public health, zoo, or wildlife personnel; and others) report diagnosed or suspected cases of [nationally listed reportable animal diseases](#) to [APHIS Area Veterinarians in Charge](#) and to the [State animal health official](#) as applicable under State reporting regulations.

Controlling Equine Infectious Anemia

[Expand All](#)

APHIS' Response

Efforts to control EIA in the United States started in 1972. Since then, the estimated national prevalence of EIA infection in the U.S. equine population has dropped from

nearly 4 percent in 1972 to 0.004 percent.

Information for Veterinarians

Only Category II accredited veterinarians, who are authorized to perform accredited duties in the State in which samples are collected, may submit samples to an APHIS-approved laboratory. You must include your National Accreditation Number (NAN) with every submission.

[Check Your Accreditation Status](#)

Submitting Samples

Accredited veterinarians must complete a VS 10-11 form either electronically or by paper using one of the USDA-approved systems or forms from the [List of Approved EIA Test Forms](#) and submit samples to [APHIS-approved labs](#). Contact your [Area Veterinarian in Charge](#) with questions. Please request paper copies of the form from your [National Veterinary Accreditation Program coordinator](#). *Note: The form is not available as a fillable PDF.*

Post-Mortem Lesions

Spleen, liver, and abdominal lymph nodes may be enlarged. Mucous membranes can be pale. In chronic cases, emaciation may also be noted. However, horses that die between clinical episodes may have no gross lesions.

Equine Infectious Anemia in Current or Former Quarter Horse Racehorses

[Equine infectious anemia](#) (EIA) is an untreatable blood-borne viral disease of horses. It has been detected and controlled in the United States since the 1970s using a

diagnostic assay called the Coggins test. Over time, the prevalence of EIA in the U.S. had been reduced to very low levels, estimated to be around 0.004% of the horse population. Historically, EIA-positive horses were primarily found in untested or undertested equine populations where natural transmission by biting flies occurred within individual herds. Since 2017, a new high-risk population for EIA infection has emerged: current or former Quarter Horse racehorses, many with ties to unsanctioned (bushtrack) racing.

The primary method of spread in this population is the human-facilitated transfer of EIA-contaminated blood or blood products from infected to uninfected horses. This is called iatrogenic transmission. It is completely preventable through basic hygiene and biosecurity measures. Common methods of iatrogenic transmission include:

- Re-use of needles, syringes, or intravenous administration equipment between horses,
- Blood-contamination of multi-dose vials of injectable medication,
- Illegal importation of blood or plasma products from other countries, and
- Direct blood transfusion between horses for the purpose of increasing athletic performance (blood-doping).

These unhygienic practices can also spread other blood-borne diseases between horses, such as [equine piroplasmiasis](#) (EP). To prevent further spread, current Quarter Horse racehorses should be regularly tested for both EIA and EP throughout their racing career. If you own current or former Quarter Horse racehorses and you don't know their status for these diseases, you should work with your veterinarian to test for EIA and EP.
